279 **ABBREVIATIONS AND ACRONYMS**

---

280	AIC	Akaike information criterion
281	BMD	Benchmark dose
282	BMDL	Benchmark dose lower bound
283	BMR	Benchmark responses
284	CSF	Cancer slope factor
285	EPA	Environmental Protection Agency
286	ER	Extra risk
287	ICR mice	Institute for Cancer Research mice
288	LOAEL	Lowest-observed-adverse-effect-level
289	NOAEL	No-observed-adverse-effect-level
290	POD	Point of departure
291	RD	Relative deviations
292	SD	Standard deviation

## 293 1 BENCHMARK DOSE MODELING RESULTS

---

294 The U.S. Environment Protection Agency (EPA or the Agency) performed benchmark dose (BMD)  
295 modeling using EPA’s BMD modeling software ([BMDS](#)), Version 3.2.0.1) for the health domains that  
296 were identified during hazard identification and that received a judgment of likely (“evidence indicates  
297 that TCEP exposure likely causes [health effect]”) and suggests (“evidence suggests but is not sufficient  
298 to conclude that TCEP exposure causes [health effect]”) during evidence integration. EPA considered  
299 that TCEP is likely to cause the following health endpoints for which BMD modeling is presented:  
300 neurotoxicity, reproductive toxicity, kidney toxicity, and cancer (kidney tumors). EPA considered that  
301 TCEP exposure results in a suggests conclusion for: mortality, liver toxicity, and developmental toxicity.  
302 EPA conducted BMD modeling in a manner consistent with EPA’s *Benchmark Dose (BMD) Technical  
303 Guidance* ([U.S. EPA, 2012](#)).  
304

305 EPA used dichotomous models to fit quantal data (*e.g.*, incidences of karyomegaly) and continuous  
306 models to fit continuous data (*e.g.*, kidney weights), as recommended by EPA’s *BMD Technical  
307 Guidance* ([U.S. EPA, 2012](#)). The BMD/BMDLs are provided based on a daily exposure (*i.e.*, seven days  
308 per week) for easier comparison across all hazard endpoints and thus, doses were adjusted as needed  
309 before BMD modeling. EPA modeled endpoints that had statistically significant pairwise comparisons  
310 between individual doses and controls or significant dose-response trends. EPA also considered potential  
311 biologically significant changes from controls where possible and/or changes that appeared to exhibit a  
312 dose-response relationship upon visual inspection. Multiple health endpoints may have been modeled  
313 from each study, depending on the relevance of the data to adverse health outcomes and to identify  
314 sensitive health endpoints for each domain.  
315

316 Although some of the data sets could be fit using models after dropping doses (either 1, 2, or 3 of the  
317 highest doses), EPA considered only modeling results from full data sets for use in quantifying risk. This  
318 document does not present results of modeling exercises in which none of the models in the BMD suite  
319 provided an adequate fit to the full data sets. Several additional endpoints evaluated in various TCEP  
320 toxicity studies were not considered for BMD modeling because the changes were observed only at the  
321 highest dose. Studies were also not considered for BMD modeling if the lowest-observed-adverse-  
322 effect-levels (LOAELs) were more than 10-times greater than the most sensitive LOAEL for the health  
323 domain. If BMD modeling was not possible or when data did not fit the available models, EPA used no-  
324 observed-adverse-effect-levels (NOAELs) and LOAELs during point of departure (POD) selection for  
325 the risk evaluation.  
326

327 EPA relied on the BMD guidance and other information to choose benchmark responses (BMRs)  
328 appropriate for each endpoint. Although the *BMD Technical Guidance* doesn’t recommend default  
329 BMRs, it describes how various BMD modeling results compare with NOAEL values, and the guidance  
330 recommends calculating 10 percent extra risk (ER) for quantal data and one standard deviation (SD) for  
331 continuous data to compare modeling results across endpoints. EPA also modeled percent relative  
332 deviations (RD) for certain continuous endpoints. EPA’s choice of BMRs for the TCEP health endpoints  
333 is described in more detail in the following sections that present BMD modeling results for each health  
334 domain.  
335

336 When modeling dose-response relationships, the data can be modeled as either ER or additional risk.  
337 EPA modeled the data as ER. EPA’s *BMD Technical Guidance* defines extra risk (ER) as “a measure of  
338 the proportional increase in risk of an adverse effect adjusted for the background incidence of the same

339 effect.” Mathematically, extra risk is equal to  $[P(d) - P(0)]/[1 - P(0)]$ . P(d) is the probability of the effect  
340 at dose d, and P(0) is the probability of risk with no exposure to a hazard (U.S. EPA, 2012).<sup>1</sup>

341  
342 Of the modeled BMDLs, critical endpoints and their PODs used as the basis of risk estimates are  
343 decreased numbers of seminiferous tubules (Section 1.1.2.1), changes in path length in the Morris water  
344 maze (Section 1.1.1.1) and increased incidence of renal tubule adenomas and carcinomas (Section  
345 1.2.1).

## 346 **1.1 Non-cancer**

---

### 347 **1.1.1 Neurotoxicity**

---

#### 348 **1.1.1.1 Path Length in the Morris Water Maze Test in Female Rats**

---

349 Path length in the Morris water maze test decreased in female rats exposed to TCEP for 60 days (Yang  
350 et al., 2018). First, the administered doses were duration adjusted to estimate an equivalent oral dose for  
351 animals exposed for seven rather than five days per week. Then, dichotomous models were used to fit  
352 dose response data.

353  
354 A BMR of 1 SD, 10, 20, and 30 percent relative deviations were modeled according to EPA’s  
355 *Benchmark Dose Technical Guidance* (U.S. EPA, 2012). EPA chose the BMR of 20 percent RD as the  
356 most appropriate measure of relevant biological change (U.S. EPA, 2022) when comparing with other  
357 PODs. The doses and response data used for the modeling are presented in Table 1-1.

358  
359 **Table 1-1. Path Length Decreased in the Morris Water Maze Test**  
360 **Selected for Dose-Response Modeling for TCEP from a 60-Day Study**

Dose (mg/kg/day)	Number of Animals	Mean	SD
0	10	685	144.90
50	10	602	106.12
100	10	470	114.28
250	10	317	110.20

361  
362 The BMD modeling results for path length in the Morris water maze test are summarized below in Table  
363 1-2. The constant variance model provided an adequate fit to the variance data. With the constant  
364 variance model applied, all models except for the Exponential 5 and Hill models provided adequate fit to  
365 the means. The BMDLs for the fit models were sufficiently close (differed by <3-fold); therefore, the  
366 model with the lowest AIC was selected. The Exponential 2 and 3 models converged on the same model  
367 and had the lowest AIC; the Exponential 2 model is the more parsimonious choice.

---

<sup>1</sup> EPA’s *BMD Technical Guidance* also uses the terms excess incidence and excess risk, which are defined more generally as increased risk or incidence above control or background responses. These terms can refer to either additional or extra risk (U.S. EPA, 2012).

**Figure 1-5. Details Regarding the Selected Model (Exponential 2) for Path Length in the Morris Water Maze Test in Female Rats Following Oral Exposure to TCEP in a 60-Day Toxicity Study**

400

**1.1.1.2 Necrosis of the Neurons of the Hippocampus in Female Rats**

401

402

403

404

405

Increased necrosis of the neurons of hippocampus was observed in female rats exposed to TCEP for 16 weeks (Matthews et al., 1990; NTP, 1991b). First, the administered doses were duration adjusted to estimate an equivalent oral dose for animals exposed for seven rather than five days per week. Then, dichotomous models were used to fit dose-response data.

406 EPA presents BMDLs based on BMRs of 5 and 10 percent ER from the best fit model. Based on the  
 407 severity of the endpoint and considering EPA’s *BMD Technical Guidance* (U.S. EPA, 2012), EPA is  
 408 using the BMDL based on a BMR of 5 percent ER for this endpoint in the risk calculation. The doses  
 409 and response data used for the modeling are presented in Table 1-3.

411 **Table 1-3. Necrosis of the Neurons of the Hippocampus Selected**  
 412 **for Dose-Response Modeling for TCEP from a 16-Week Study**

Dose (mg/kg/day)	Number of Animals	Incidence
0	10	0
16	10	0
31	10	0
63	10	0
125	10	8
250	10	10

413 The BMD modeling results for the necrosis of neurons in the hippocampus are summarized in Table 1-4.  
 414 All models, except for the 1-degree Multistage model, provided an adequate fit (chi-square p-value >  
 415 0.1) to the data. Using a BMR of 10 percent extra risk, the BMDLs for the fit models were sufficiently  
 416 close (differed by < 3-fold); therefore, the model with the lowest AIC (Probit) was selected. Using a  
 417 BMR of 5 percent extra risk, however, BMDLs for the fit models differed by > 3-fold and the BMDS  
 418 software recommended selection of the 2-degree Multistage model because it estimated the lowest  
 419 BMDL. Although the 2-degree Multistage model provided overall adequate fit to the data, in the context  
 420 of this data set, the high residuals at the key datapoints (-1.7 and 1.1) indicate a relatively poor fit in the  
 421 key part of the dose-response curve. For this reason, the 2-degree Multistage was dropped from  
 422 consideration. The BMDLs of the remaining models are sufficiently close (differed by < 3-fold), and the  
 423 model with the lowest AIC (Probit) was selected.

**Figure 1-8. Details Regarding the Selected Model (Probit) for Necrosis of the Neurons in the Hippocampus in Female Rats Following Oral Exposure to TCEP in a 16-Week Chronic Toxicity Study**

**1.1.1.3 Serum Cholinesterase Activity in Female Rats**

Serum cholinesterase activity was decreased in female rats that were exposed to TCEP for 16 weeks (NTP, 1991b). First, the administered doses were duration adjusted to estimate an equivalent oral dose for animals exposed for seven rather than five days per week. Then, continuous models were used to fit dose-response data.

EPA modeled serum cholinesterase activity for BMRs of 1 SD and 10 percent RD according to EPA’s *Benchmark Dose Technical Guidance* (U.S. EPA, 2012). The doses and response data used for the modeling are presented in Table 1-5.

456  
457

**Table 1-5. Decrease of Serum Cholinesterase Activity Selected for Dose-Response Modeling for TCEP from a 16-Week Study**

Dose (mg/kg/day)	Number of Animals	Mean	SD
0	10	2064	354.18
16	8	1946	353.55
31	10	1808	332.04
63	10	1873	332.04
125	8	1550	294.16

464  
465  
466

The BMD modeling results for serum cholinesterase activity are summarized in Table 1-6. The constant variance model did not provide adequate fit to the variance data, but the non-constant variance model did fit. With the non-constant variance model applied, all the models provided adequate fit to the means (test 4 p-value > 0.1). The BMDLs for the fit models were sufficiently close (differed by < 3-fold); therefore, the model with the lowest AIC was selected.

485 **Cholinesterase Activity Decreases in Female Rats Following Oral Exposure to**  
486 **TCEP in a 16-Week Chronic Toxicity Study**

487 **1.1.2 Reproductive and Developmental Toxicity**

488 EPA modeled endpoints when one or more doses showed pairwise differences from controls and/or  
489 when a dose-response trend was evident in the data. EPA modeled litter data separately by sex as well as  
490 combined (males and females) as well as effects on male reproductive organs.

491  
492 EPA did not present the BMD modeling results for several endpoints from [NTP \(1991a\)](#) that resulted in  
493 inadequate model fits. These endpoints included several for the F0 animals: cumulative days to litter  
494 (litter numbers 2 and 3); mean litters per pair; and live F1 pups per litter (both sexes and females). Also,  
495 although F1 fertility was modeled due to a statistically significant dose-response trend, the results are  
496 not presented because the BMD/BMDL ratio was greater than three and the BMDL was more than three  
497 times lower than the lowest dose tested. Testicular testosterone levels from [Chen et al. \(2015\)](#) were  
498 modeled but didn't fit any of the constant or non-constant variance models.

499

500 EPA also identified an anomaly in the data presented Table 4-4 within [NTP \(1991a\)](#) that affects the  
501 measures of sex of F2 pups born alive and live male F2 pups per litter (difference in proportion of males  
502 at 350 mg/kg-day). Therefore, although EPA modeled both effects (with an adequate model fit for live  
503 male F2 pups per litter), EPA is not presenting the results base on the identified error.

504 **1.1.2.1 Decreased Numbers of Seminiferous Tubules (Mice)**

505 [Chen et al. \(2015\)](#) found decreases in numbers of seminiferous tubules in adolescent ICR mice after 35  
506 days of exposure. Continuous models were used to fit data, and BMDLs based on BMRs of one SD and  
507 five percent RD from the best fit model are both presented. Based on the severity of the endpoint  
508 (considering EPA’s *BMD Technical Guidance (U.S. EPA, 2012)*), EPA is using the BMDL based on a  
509 lower BMR (EPA used five percent RD) for this endpoint in the risk calculation. The doses and response  
510 data used for the modeling are presented in Table 1-7. There is uncertainty in using the BMDL based on  
511 a BMR of 5 percent because this BMR is lower than the responses observed in the study (decreases of  
512 22.2 and 40.7 percent at 100 and 300 mg/kg-day, respectively).

513

514 **Table 1-7. Decreased Numbers of Seminiferous Tubules in Mice and Associated**  
515 **Doses Selected for Dose-Response Modeling for TCEP**

Dose (mg/kg-day)	Number of Mice	Mean	SD
0	7	24.3	5.29
100	7	18.9	3.17
300	7	14.4	2.65

516

517 Table 1-8 summarizes the BMD modeling results for decreased numbers of seminiferous tubules from  
518 [Chen et al. \(2015\)](#). The constant variance model provided adequate fit to the variance data and with this  
519 model applied, all models except the Exponential 4 and 5 models, provided adequate fit to the means (p-  
520 value > 0.1). BMDLs for the fit models were sufficiently close (< 3-fold difference). Therefore, EPA  
521 selected the model with the lowest Akaike information criterion (AIC). The software selected the  
522 Exponential 3 model, but EPA chose the Exponential 2 as the more parsimonious choice because  
523 Exponential 3 defaulted to the Exponential 2 model by bounding variable d at a value of one.

524

525 **Table 1-8. Summary of BMD Modeling Results for Decreased Numbers of Seminiferous Tubules**

546

**1.1.2.2 Decreases in Testes Weights (Mice)**

547

[Chen et al. \(2015\)](#) identified decreased testes weights in adolescent ICR mice after 35 days exposure to TCEP. Continuous models were used to fit dose-response data. BMDLs based on BMRs of one SD and five percent RD from the best fit model are both presented. Based on EPA's *BMD Technical Guidance* ([U.S. EPA, 2012](#)), EPA is using the BMDL based on a BMR of one SD for this endpoint when comparing with other points of departure. The doses and response data used for modeling this endpoint are presented in Table 1-9.

552

553

554

555

**Table 1-9. Decreased Testes Weights in Mice and Associated Doses Selected for Dose-Response Modeling for TCEP**

Dose (mg/kg-day)	Number of Fertile Pairs	Mean	SD
0	7	0.32	0.053
100	7	0.28	0.04
300	7	0.27	0.019

556

557 Table 1-10 summarizes the BMD modeling results for decreased testes weights from [Chen et al. \(2015\)](#).  
 558 The constant variance model did not provide adequate fit to the variance data, but the non-constant  
 559 variance model did. With the non-constant variance model applied, all models except the Exponential 4  
 560 and 5 models provided adequate fit to the means. The BMDLs for the fit models were sufficiently close  
 561 (< 3-fold difference). therefore, EPA chose the Exponential 3 model, the one with the lowest AIC was  
 562 selected.

563

656 **Mice in a Continuous Breeding Study**

657 **1.1.2.5 F0 Fertility in Mice**

658 [NTP \(1991a\)](#) identified increases in the number of non-fertile pairs per number of cohabiting mice for  
659 litter five from the F0 generation. Dichotomous models were fit to the incidence data. EPA chose a  
660 BMR of five percent ER according to EPA's *BMD Technical Guidance* ([U.S. EPA, 2012](#)) to compare

661 with other points of departure. The doses and response data used for the modeling are presented in Table  
 662 1-15.

663 **Table 1-15. F0 Non-fertility in Mice and Associated Doses Selected for**  
 664 **Dose-Response Modeling for TCEP**  
 665

Dose (mg/kg-day)	Number of Animals Cohabiting	Incidence of Nonfertility
0	38	3
175	19	2
350	18	5
700	18	18

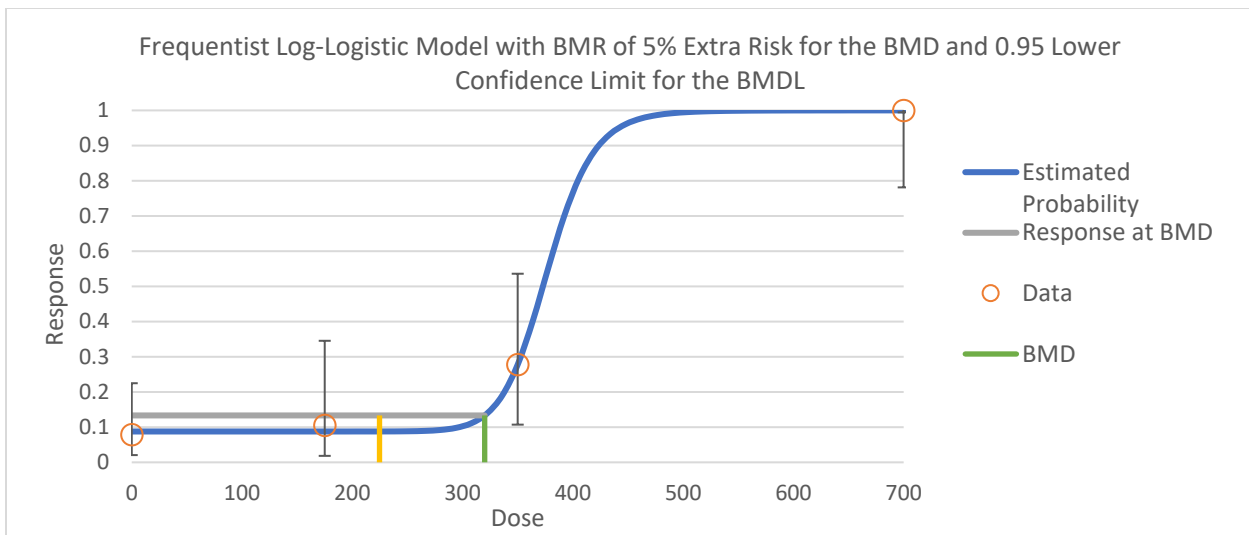

666 Table 1-16 summarizes the BMD modeling results for F0 non-fertile mice from [NTP \(1991a\)](#). The  
 667 Dichotomous Hill, Gamma, Log-logistic, 3-degree Multistage, Weibull, and Log-probit models provided  
 668 an adequate fit (chi-square p-value > 0.1) to the data. The BMDLs for the fit models were sufficiently  
 669 close (differed by < 3-fold). Therefore, EPA chose the model with the lowest AIC.  
 670

### 686 **1.1.3 Kidney Toxicity**

687 EPA selected multiple kidney endpoints for quantitative dose-response analysis with BMDS, including  
688 histopathological lesions and kidney weights. EPA modeled kidney weight changes when a pairwise  
689 change from controls and/or dose-response trend was evident in the data (*e.g.*, a statistically significant  
690 change was identified). The best measures are kidney weight changes relative to body weight (to  
691 account for any changes that are primarily related to body weight changes). EPA presents the female rat  
692 relative kidney weight data from the 16-week [NTP \(1991b\)](#) study after dropping the highest dose from  
693 the models and considers this to be appropriate due to the decreased survival at the highest dose (5 of 10  
694 animals died). However, EPA could not model the female rat absolute kidney without dropping the *two*  
695 highest doses and therefore, EPA is not presenting these data. In the 16-week study ([NTP, 1991b](#)), male  
696 kidney weights were increased only at the highest doses and therefore, EPA did not conduct BMD  
697 modeling for these changes.

698

### 1.1.3.1 Renal Tubule Hyperplasia in Male Rats

699

There was an increased incidence of renal tubule hyperplasia in male rats exposed to TCEP for two years in a chronic toxicity study by [NTP \(1991b\)](#). First, the administered doses were duration adjusted to estimate an oral dose for animals exposed for seven days per week rather than five days per week. Then, dichotomous models were used to fit dose-response data.

703

704

A BMR of 10 percent ER was chosen according to *BMD Technical Guidance* ([U.S. EPA, 2012](#)). The doses and response data used for the modeling are presented in Table 1-17.

706

707

708

### 1.1.3.5 Relative Kidney Weight in Female Rats

820

Relative kidney weights increased in female mice exposed to TCEP for 16 weeks ([NTP, 1991b](#)). For  
821 BMD modeling, the administered doses were first duration adjusted to estimate an equivalent oral dose  
822 for animals exposed for seven days per week rather than five days per week. Then, continuous models  
823 were used to fit dose-response data.

824

825

A BMR of one SD were chosen according to EPA's *BMD Technical Guidance* ([U.S. EPA, 2012](#)). EPA  
826 did not identify a specific magnitude of change in relative kidney weight (*e.g.*, 10 percent) that would be  
827 considered biologically significant. The doses and response data used for the modeling are presented in  
828 Table 1-25.

829

830  
831

**Table 1-25. Female Rat Relative Kidney Weights and Associated Doses Selected for Dose-Response Modeling for TCEP From a 16-Week Study<sup>a</sup>**

Dose (mg/kg-day)	Number of Animals	Mean	SD
0	10	3.69	0.13
16	8	3.83	0.17
31	10	4.03	0.13
63	10	4.1	0.22
125	8	4.18	0.17

<sup>a</sup> The following data for the top dose of 250 mg/kg-day was not used: 5 animals, mean and SD of 4.51 and 0.13.

832

833 Table 1-26 summarizes the BMD modeling results for increased relative kidney weight in female rats in  
 834 the 16-week study. For the full data set (using all dose groups), none of the available models provided  
 835 adequate fit to the means (test 4 p-value < 0.1). Survival was decreased at the highest dose and EPA  
 836 considered that the models could be run using the control and four lower doses. Although data are not  
 837 available on the cause of all the deaths, two females died after receiving double doses for three days and  
 838 several of the overdosed animals; the cause of deaths of three other female rats was not stated. Without  
 839 the highest dose, the constant variance model provided adequate fit to the variance data (test 2 p-values  
 840 > 0.05) and with the model applied, the Exponential 4 and 5 models provided adequate fit to the means  
 841 (test 4 p-value > 0.1). The BMDLs for the fit models were sufficiently close (differed by < 3-fold);  
 842 therefore, EPA selected the model with the lowest AIC (Exponential 4).

843

844 **Table 1-26. Summary of BMD Modeling Results for Increased Relative Kidney Weights in Female**

857

858 **Figure 1-35. Details Regarding the Selected Model (Exponential 4) for Relative Kidney Weight**  
859 **Increases in Female Rats Following Oral Exposure to TCEP in a 16-Week Toxicity Study**

860 **1.1.4 Liver Toxicity**

861 EPA modeled liver effects when a pairwise change from controls and/or dose-response trend was  
862 evident in the data (*e.g.*, a statistically significant change was identified).

863  
864 When modeling liver weight changes, the best measures are changes relative to body weight (to account  
865 for any changes that are primarily related to body weight changes). However, EPA modeled both  
866 relative and absolute liver weight changes in male rats at 66 weeks in the two-year cancer bioassay and  
867 in female rats and mice from 16-week studies ([NTP, 1991b](#)) because body weights didn't change or

868 because the percent change in relative liver weight was 30 percent greater than changes in body weight  
 869 in female rats at 350 mg/kg-day after 16 weeks.

870  
 871 All modeled results from the NTP studies are presented except the relative liver weight changes in male  
 872 rats at 66 weeks because neither the constant nor the non-constant variance models provided adequate fit  
 873 to the variance data. The female rat data could not be modeled without dropping doses and therefore,  
 874 EPA is not presenting these data. EPA also modeled decreased absolute liver weight in male ICR mice  
 875 in a 35-day study ([Chen et al., 2015](#)) as a comparison with liver weight changes from other studies, but  
 876 these results are not shown because none of the models provided adequate fits to the data either  
 877 assuming constant or non-constant variance.

#### 878 **1.1.4.1 Eosinophilic Foci in Male Mice**

879 Male mice exhibited an increase in eosinophilic liver foci after two years of exposure to TCEP ([NTP,  
 880 1991b](#)). As inputs to BMD modeling and for consistency across endpoints, administered doses were first  
 881 duration adjusted to estimate an equivalent oral dose for animals exposed for seven days per week rather  
 882 than five days per week. Then, dichotomous models were used to fit dose-response data.

883  
 884 EPA presents the BMDL based on a BMR of 10 percent ER from the best fit model and based on the  
 885 severity of the endpoint and considering EPA’s *BMD Technical Guidance* ([U.S. EPA, 2012](#)). The doses  
 886 and response data used for the modeling are presented in Table 1-27.

887  
 888 **Table 1-27. Male Mouse Eosinophilic Foci in Livers and Associated Doses**  
 889 **Selected for Dose-Response Modeling for TCEP in the Two-Year**  
 890 **Bioassay**

Dose (mg/kg-day)	Number of Animals	Incidence
0	50	0
125	50	3
250	50	8

891  
 892 Table 1-28 summarizes the BMD modeling results for eosinophilic foci in male mice. The Log-logistic,  
 893 Multistage 2- and 1- degree, Logistic, and Probit models all provided adequate fits to the data (chi-  
 894 square p-value > 0.1). BMDLs among the fit models were sufficiently close (< 3-fold difference).  
 895 Therefore, EPA chose the model with the lowest AIC – the Multistage 1-degree model.

896

911 **1.1.4.2 Absolute Liver Weight in Male Rats**

912 Absolute liver weights increased in male rats exposed to TCEP at 66 weeks ([NTP, 1991b](#)). As inputs to  
913 BMD modeling and for consistency across endpoints, administered doses were first duration adjusted to  
914 estimate an equivalent oral dose for animals exposed for seven days per week rather than five days per  
915 week. Then, continuous models were used to fit dose-response data.

916  
917 BMRs of one SD and ten percent RD were chosen according to EPA's *BMD Technical Guidance* ([U.S.](#)  
918 [EPA, 2012](#)). EPA considers the BMR of ten percent RD to be adverse and used the BMDL associated  
919 with this BMR for consideration within the risk evaluation and when comparing with other PODs. The  
920 doses and response data used for the modeling are presented in Table 1-29.

932

933

Table 1-30 summarizes the BMD modeling results for increased absolute liver weight in male rats at 66 weeks in the NTP two-year chronic bioassay. Although the constant variance model did not provide adequate fit to the variance data, the non-constant variance model provided an adequate fit. With the non-constant variance model applied, the Exponential 2, Exponential 3, 2-degree Polynomial, Power and Linear models provided adequate fit to the means (test 4 p-value > 0.1). The BMDLs for the fit models with adequate fit were sufficiently close (< 3-fold difference). The Power and 2-degree Polynomial models converged on the Linear model; these had the lowest AICs and the Linear model was selected as the most parsimonious choice.

934

955

**1.1.4.3 Absolute Liver Weight in Female Mice**

956

Absolute liver weights increased in female mice exposed to TCEP for 16 weeks (NTP, 1991b). For BMD modeling, the administered doses were first duration adjusted to estimate an equivalent oral dose for animals exposed for seven days per week rather than five days per week. Then, continuous models were used to fit dose-response data.

959

960

961

BMRs of one SD and ten percent RD were chosen according to EPA's *BMD Technical Guidance* (U.S. EPA, 2012). EPA considers the BMR of ten percent RD to be adverse and used the BMDL associated with this BMR for consideration within the risk evaluation and when comparing with other PODs. The doses and response data used for the modeling are presented in Table 1-31.

Table 1-32 summarizes the BMD modeling results for increased absolute liver weight in female mice in the 16-week study. The constant variance model provided adequate fit to the variance data. With the constant variance model applied, the Exponential 4 and 5 models and the Hill model provided adequate fit to the means. The BMDLs for these models were sufficiently close (< 3-fold difference). Therefore, EPA selected the Exponential 4 model because it has the lowest AIC.

### 1.1.4.4 Relative Liver Weight in Female Mice

999 Relative liver weights increased in female mice exposed to TCEP for 16 weeks (NTP, 1991b). For BMD  
1000 modeling, the administered doses were first duration adjusted to estimate an equivalent oral dose for  
1001 animals exposed for seven days per week rather than five days per week. Then, continuous models were  
1002 used to fit dose-response data.

1003  
1004 BMRs of one SD and 10 percent RD were chosen according to EPA’s BMD Technical Guidance (U.S.  
1005 EPA, 2012). EPA considers the BMR of ten percent RD to be adverse and used the BMDL associated  
1006 with this BMR for consideration within the risk evaluation and when comparing with other PODs. The  
1007 doses and response data used for the modeling are presented in Table 1-33.

1008  
1009 **Table 1-33. Female Mouse Relative Liver Weights and Associated Doses Selected**  
1010 **for Dose-Response Modeling for TCEP From a 16-Week Study**

500	10	47.4	3.29

1011

1012 Table 1-34 summarizes the BMD modeling results for increased relative liver weight in female mice in  
1013 the 16-week study. The Exponential 4 and 5 models and the Hill model provided adequate fit to the  
1014 means (test 4 p values > 0.1) using the constant variance model. The BMDLs for these models differed  
1015 by less than 3-fold, and therefore, EPA chose the Exponential 5 model because it has the lowest AIC.

1016

**Figure 1-46. Details Regarding the Selected Model (Exponential 5) for Relative Liver Weight Increases for Female Mice Exposed in a 16-Week Study**

## 1.2 Cancer

EPA modeled endpoints for kidney tumors, the only tumors that had robust evidence if one or more doses resulting in pairwise differences from controls and/or if a dose-response trend was evident in the two-year cancer bioassay (NTP, 1991b). Evidence for tumors at other target organs was slight. The BMD/BMDLs chosen for tumor incidence were based on animals still alive at the time the first incidence of cancer was observed. Also, preference was given to presenting BMD models that included both adenomas and carcinomas because benign tumors (adenomas) are expected to lead to malignant tumors (carcinomas).<sup>2</sup>

EPA did not present BMD modeling after combining tumors from multiple target organs, because the combinations would include tumors for which evidence was slight.

### 1.2.1 Renal Tubule Adenomas and Carcinomas (Combined) in Male Rats

Male rats exhibited increased incidences of renal tubule carcinomas and adenomas in the two-year NTP bioassay (NTP, 1991b). For BMD modeling, the administered doses were first duration adjusted to estimate an equivalent oral dose for animals exposed for seven rather than five days per week. Then, two Multistage models were used to fit dose-response data.

EPA chose a BMR of 10 percent ER to model the tumor data according to EPA's *Benchmark Dose Technical Guidance* (U.S. EPA, 2012). The doses and response data used for the modeling using both kidney adenomas and carcinomas are presented in Table 1-35. The numbers of animals were adjusted for mortality. Specifically, the modeling included only the animals still alive when the first tumor was observed (day 575).

**Table 1-35. Male Rat Renal Tubule Adenomas or Carcinomas (Combined) and Associated Doses Selected for Dose-Response Modeling for TCEP from a Two-Year Chronic Bioassay**

Dose (mg/kg-day)	Number of Animals	Incidence <sup>a</sup>
0	40	2
31	44	5
63	44	25

<sup>a</sup> Increased incidence of carcinoma was identified – 1 control and 1 high-dose rat

Table 1-36 summarizes the BMD modeling results for combined renal tubule adenomas and carcinomas in male rats. EPA selected the 2-degree Multistage model because it was the only model that provided an adequate fit (chi-square p-value > 0.1) to the data.

<sup>2</sup> As a comparison, EPA also conducted BMD modeling of tumor incidence from an 18-month dietary study using ddY mice (Takada et al., 1989) (not shown). Tumors included: Renal cell adenomas and carcinomas in males; hepatocellular adenomas and carcinomas in males; leukemia in females; and forestomach papillomas and squamous cell carcinomas in females. Takada et al. (1989) is in a foreign language and was not critical to using quantitatively in the risk evaluation; furthermore, EPA did not evaluate it for data quality. One or more of the multistage models fit each of these tumor type/sex combinations but ddY mice were less sensitive than the species used by NTP (1991b) based on the resulting cancer slope factors (CSFs).
